

DRUG SIDE EFFECTS ANALYSIS DASHBOARD

Power BI Mini Project

1. Project Objective

The objective of this project is to analyse drug side-effect data and identify patterns related to adverse reactions, severity levels, hospitalization rates, recovery outcomes, and patient demographics. The dashboard helps healthcare professionals and researchers understand the impact of different drugs on patients and supports data-driven decision-making.

2. Dataset Description

Dataset contains patient demographics, drug information, side effects, severity levels, hospitalization status, outcomes, treatment dates, and recovery information. Total records analysed: 30,000.

3. Data Cleaning Process

Removed duplicates, handled missing values, standardized categories, corrected formats, converted date fields, created age groups, and developed DAX measures for KPI calculations

4. Tools Used

- Microsoft Excel- for Data Cleaning, Data Transformation.
- Microsoft Power BI- for DAX, Dashboard Design, and Data Visualization.

5. Key Insights

Middle-aged patients form the largest group. Nausea is the most common side effect. Mild cases account for the majority of reports. Severe cases contribute significantly to hospitalizations. Recovery time generally increases with severity.

6. Conclusion

The dashboard provides an interactive solution for monitoring drug side effects, understanding patient outcomes, and supporting healthcare decision-making.
